6. Opening Protection

You can protect your home’s openings, such as windows and doors, from penetration by windborne debris by installing impact-resistant windows and doors or installing impact resistant coverings, such as shutters over windows and doors.

Impact resistant glass and shutters are specifically designed to meet a combination of impact and continuous pressure from the wind. Always use products that have been tested to one of these standards and have been designated as such through a recognized product approval system or evaluation report: SRCC SSTD 12 ASTM E 1886 and ASTM E 1996 Miami-Dade Protocols PA 201, PA 202, and PA 203.

Equally important as the strength of the glass or shutter is the strength of the window’s frame and attachment hardware. Opening protection devices are tested as a unit that includes the glass, the frame, as well as the attachment hardware and the installation method. Impact resistant windows and shutters should always be installed following the manufacturer’s recommendations.

7. Doors

Exterior doors should also be wind and impact resistant or protected with an impact resistant covering.

Garage doors are particularly vulnerable to high winds, because of the long span of opening they cover and the relatively lightweight material they are made of. Two options are available for strengthening garage doors.

together to form a ridge or a peak at the top – each end looks like the letter A. Homes with gabled roofs are more likely to suffer damage, such as collapse of the end wall from high winds because they are often not braced properly during construction. If your home is built with a gabled end wall, use one of the following construction techniques.

- **Continuous Wall Construction** or Balloon Framing – Use full-height studs, concrete or solid masonry walls from the floor below all the way up to the roof. Balloon-framed gable end walls perform better in windstorms because they do not have the hinge that usually exists where the triangular part of the gable sits on top of the wall below. Homes with high, cathedral-like ceilings, where there is no place to brace a gabled end, should be balloon framed, or will require a special design by a registered or licensed engineer.

- **Platform Framing** – Brace the intersection of the gable and the end wall. This intersection is a particularly weak point and those that are not properly braced can collapse, causing major damage, allowing wind and wind-driven rain into the home. In homes with attics, an attic floor or ceiling diaphragm with the proper bracing techniques can be used to provide the lateral support of the gable end wall if the end wall is NOT framed full height.

1. **Roof Deck and Attachment**
   The roof covering, and the deck beneath it, are your home’s first line of defense and form a critical shield of protection from high winds and rain. The following techniques should be used during roof installation on both new and existing homes, and are best performed by a licensed, professional roofing contractor.

   - Install a roof deck of solid plywood – 5/8” thickness to maximize wind and windborne debris resistance with 10 penny common or 8 penny ring Shank nails spaced at 4 inches along the panel edges and every six inches in the field of the plywood panel. Make sure that the nails penetrate the decking directly into the roof framing.
   - Be sure to look in the attic to confirm that the roof decking is properly nailed to the roof framing. If you can see nails along the sides of rafters or trusses, where the nail penetrates the decking, your roof deck is probably not securely attached.

2. **Secondary Water Barrier**
   Even though roof coverings are somewhat wind resistant, a secondary water barrier provides protection if the covering is damaged or is blown off.

   - Create a secondary water barrier by installing self-adhering flashing tape or modified polymer bitumen strips on top of the joints in your roof deck. This will help keep out the rain in the event the roof covering is damaged or destroyed by severe weather.
   - Install one layer of #30 underlayment – sometimes called felt paper – over the roof decking and secondary water barrier. The felt helps with drainage in the event water gets under the roof covering.

3. **Roof Covering**
   - Install a roof covering that has been tested to the latest standards for wind and hail resistance. These standards are: ASTM D 3161 enhanced or UL 2390 for wind resistance and UL 2218 for impact resistance.
   - Be sure to specify these standards and look for labels on the products confirming these standards because ordinary roofing materials may not look any different from the wind resistant versions.

4. **Roof Shape and Bracing Gabled Ends**
   The type and shape of the roof on your home can help determine how well it will perform during a severe windstorm.

   A hipped roof typically performs better in windstorms than a gabled roof because of its aerodynamic properties and typical construction techniques.

   - **Continuous Wall Construction or Balloon Framing** – Use full-height studs, concrete or solid masonry walls from the floor below all the way up to the roof. Balloon-framed gable end walls perform better in windstorms because they do not have the hinge that usually exists where the triangular part of the gable sits on top of the wall below. Homes with high, cathedral-like ceilings, where there is no place to brace a gabled end, should be balloon framed, or will require a special design by a registered or licensed engineer.

   - **Platform Framing** – Brace the intersection of the gable and the end wall. This intersection is a particularly weak point and those that are not properly braced can collapse, causing major damage, allowing wind and wind-driven rain into the home. In homes with attics, an attic floor or ceiling diaphragm with the proper bracing techniques can be used to provide the lateral support of the gable end wall if the end wall is NOT framed full height.

5. **Roof to Wall Connections**
   Your home’s ability to resist the extreme force of wind is only as strong as its weakest link, so the only sure way to create a wind-resistant home is to secure all connections – roof-to-wall, floor-to-floor and wall-to-foundation.

   The roof is your home’s first line of defense from a storm. To make sure the roof stays in place when severe winds blow, securely anchor the roof to the wall by installing hurricane straps or clips at every wall-to-rafter (or truss) connection to reinforce the roof. These connections are critical in holding the roof together and will dramatically increase the home’s overall resistance to wind. Be sure to install all connectors following manufacturer’s specifications.
